Being the most abundant natural source of energy, solar energy is considered the future of the global renewable energy sector. However, unlike direct utilisation of solar energy (for example, daylighting applications), energy converted utilisation of solar energy is limited to the low energy density of input solar radiation for the required conversion, which can be either thermal or electrical. With the global urbanisation expansion, the area utilisation of these solar power conversion systems and their environmental impacts is also becoming a major concern [1, 2]. The most straightforward approach that can be adopted to address this issue is concentrating solar radiation on a finite area using techniques of optical light concentration [3, 4]. Through the ages, the designs for solar light concentration evolved from imaging optics (mirrors and lenses) [6,8] to modern planar Fresnel optics [9,10]. However, the conventional optics systems suffer from bulkiness and cost-effectiveness due to the...
