Overview

This intentional interface is designed to manage shear forces and is structurally superior to an unplanned cold joint. While often dismissed as purely aesthetic blemishes, a cold joint is, fundamentally, a failure of integration—a plane of weakness that interrupts the essential structural continuity in columns that is vital for resisting bending, shear, and axial compression. This comprehensive guide from B. This discontinuity occurs because the older material has passed its initial setting time, preventing a true chemical bond with the fresh mix. Understanding the causes and implications of cold joints is essential for implementing effective preventive measures and ensuring the long-term performance of concrete structures. A cold joint occurs when fresh concrete is placed against hardened concrete, creating a weak bond between the two. The behaviour of the interface between two concrete layers, subjected to shear, is a complex process that is influenced by many different parameters.
